

Assignment – 1: Narrative Analysis of Renewable Energy Dataset

Name: Khushi Chadda	SAP ID: 70022300225
Roll No: D040	Class: BTech CE ‘A’

Month	Energy Output (MWh)	Cost per MWh (\$)
1	1200	58
2	1250	57
3	1180	59
4	1300	56
5	1350	55
6	900	72
7	1000	68
8	1400	50
9	1600	46
10	1750	42
11	1800	40
12	1900	38

2. Identifying the Narrative Moments

Change:

The overall dataset shows a clear change from moderate energy production and relatively high operating costs to much higher production and lower costs. Energy output increases from 1,200 MWh in Month 1 to 1,900 MWh in Month 12, while the cost falls from \$58/MWh to \$38/MWh.

Conflict:

The major conflict occurs in Month 6, when a storm damages the turbine. Energy output suddenly drops from 1,350 MWh to only 900 MWh, while the cost increases sharply from \$55/MWh to \$72/MWh. This is the weakest point in the entire dataset.

Surprise:

The surprising part is the rapid recovery after the storm. Instead of continuing to struggle, the

project begins improving quickly. By Month 8, output reaches 1,400 MWh and the cost falls to \$50/MWh, which is even better than the situation before the storm.

Turning Point:

Month 8 is the main turning point. The \$2 million turbine upgrade becomes operational, and the project moves from recovery to strong growth. After this point, output keeps increasing while cost keeps decreasing.

Resolution:

From Month 8 to Month 12, the project shows consistent improvement. Output rises from 1,400 to 1,900 MWh, while cost falls from \$50 to \$38/MWh. The project ends the year in its strongest position.

Storyline:

The dataset tells the story of a wind farm that starts the year with steady but moderate performance. During the first five months, energy production generally increases from 1,200 MWh to 1,350 MWh, while the cost per MWh gradually decreases from \$58 to \$55. However, the situation suddenly changes in Month 6 when a storm damages the turbine. This creates the main conflict in the story, as energy production falls sharply to 900 MWh and the cost rises to \$72 per MWh. The project faces a difficult period in Month 7 as it begins recovering, but the major turning point comes in Month 8 when a \$2 million turbine upgrade becomes operational. The upgrade produces an unexpectedly strong recovery: output jumps to 1,400 MWh and the cost falls to \$50 per MWh. From this point onward, the project enters a period of continuous improvement, with energy output increasing every month and the cost steadily decreasing. By Month 12, the wind farm reaches its highest output of 1,900 MWh and its lowest cost of \$38 per MWh. Therefore, the story is about how a renewable energy project faces a sudden setback, responds through investment and improvement, and ultimately becomes more productive and cost-efficient than it was at the beginning of the year.
